

Viral Friend Generator Script Installation Wizard

This Tutorial will walk you through the Viral Friend Generator installation process.

There are 3 steps that you have to do:

STEP I :

1. Upload the content of zip archive to your public html folder or any other folder you desire. Please login into your site's FTP and upload all files contained in the zip archive and upload them either direct to your public_html folder on your server, either to a sub-folder of public_html folder.

2. Change CHMOD to 777 for Templates Folder AND ALL Files contained inside the templates folder. Also change CHMOD for Config Folder AND FOR constants.php (which can be found in config folder) to 777 while installing and after install is finished change to 755.

After you've uploaded all files, please right click on templates folder and you will see in the window which opens after right-clicking Properties/CHMOD. Please click on this option and fill in the Permissions field with the number 777. The same you do with the files contained by the folder.

In order to do the installation please go to www.YourDomain.com/folder/install/index.php After you finished all installing steps please come back and change CHMOD to 755 for security issues, but ONLY for config folder and constants.php. DO NOT do this for templates folder or any files contained in the templates folder.

3. Create an empty database
Please Login to your site's Cpanel and click on Mysql® Databases.
Next you have to create a new database by entering a name for the database and pressing the Create button. Then click Go back button.
Now you have to create a user. So please fill the username and password fields and click on create button. Click Go back button again.
Now you will see displayed: Add users to database. Here select the user and the database which you created at the previous steps and click on Add user to database button.
Please make sure you take notes in a safe place of your username, password and database name you just created as you will need them in the future.
Now, you can log out from cpanel.

STEP II : Check Database Settings

Make sure to precede the database name and the username with your FTP LOGIN Username.

Let's assume you have a FTP username of **happy** then the following applies (in your case replace the word "happy" with your particular FTP username).

If you create a **database called vfgdbase** and a database **username called tester** (of course you can give any name you wish to the database and to the database username. Vfgdbase and tester, are used just for example purpose), THEN you need to entry:

DB Username: **happy_tester**

DB Name: **happy_vfgdbase**

DB Password.....enter the password you created in cpanel at previous step.

DB Host.....enter your database host, which is usually localhost.

Login email.....choose and enter a valid email

Login password.....choose and enter a valid password

Please make sure you notes in a safe place of the email and password you just entered and then click on Check Settings button. Then if you entered the correct details you will see the message: Database ok , please click Next to continue, so click on Next Step button.(if not please reenter the details and click on Recheck Settings button).

STEP III : Installation Completed - Please Delete the install Folder and Then Go to the site.

Now, please go back to your site's ftp and go in public_html folder or the sub-folder where you uploaded the zip archive content. Here you will see a folder named install. Please delete it by pressing the delete button or right-click on the folder and press delete option.
